a Preprocessing: annotation mask D, metacells, highly variable genes, expression G

b Metacells raise read depth: single cells vs metacells (summed counts of member cells)

UMIs = total counts per unit; genes detected = genes with count > 0. Metacell profile = sum of member-cell counts over all genes of the matrix (not only HVGs).
Visual: Adult atlas, glia (G_*) removed; CX: T2 atlas, cells of the best build; motor: adult t3, preMN + MN source tables are already corrected ("cg_corrected", ~1/3 non-integer entries), so motor 'UMIs' are corrected counts. Gene universes differ between systems; compare cells vs metacells within a system.
